Date of submission – February 2001
Abstract

Accompanying the ever-growing reliance on computers within contemporary organisations, the task of software maintenance is, increasingly, becoming a resource burden. The author has identified that there is a need for proven techniques to allow the modelling of flexible/changing user requirements, to enable systems to cope with requirements creep without suffering major code change and associated down-time from rebuilds of the database.

This study ascertains the applicability of extension to current data modelling techniques that allows innate flexibility within the data model. The extension of the data model is analysed for potential benefits in the provision of such a dynamic/flexible base to realise ‘maintenance friendly’ systems and, in consequence, alleviate the cost of later, expensive maintenance.
Declaration

I certify that this thesis does not, to the best of my knowledge and belief:

(i) incorporate without acknowledgement any material previously submitted for a degree or diploma in any institution of higher education;

(ii) contain any material previously published or written by another person except where due reference is made in the text; or

(iii) contain any defamatory material

Acknowledgements

I would like to take this opportunity to acknowledge and thank all the people who have helped and assisted me in this work. However there are some people to whom I wish to express particular gratitude.

Thank you to my supervisor, Michael Collins, for all your time and effort, I couldn’t have done this without you. "Unus, sed leo!" [One, but a lion!] Aisopos (Fabulae 194). Also, thanks must go to Celia for letting me borrow him.

Thank you to my family: to Mum, for always believing in me and giving me so much love and support; to Dad, for all your guidance and for giving me a hunger for knowledge, without which I could have never become who I am today; and to my brother Michael just for being himself.

Thank you to all my friends who have been there when I needed support or to let off steam. Especially Johanna, Jeremy, Troy, Cameron, David, Katie, Dominique, Rachael, Sarah, Bonnie, Todd, Joanne, Nikki and Mr ‘M’ for letting me crash at his pad.

Thank you to all the teachers that have inspired me through the years: especially to Jean Hall, Penny Cookson, Julian Terry, and John Doyle.

And finally to the Authors whose books have inspired me and fuelled my imagination, as Albert Einstein once said: “Imagination is more important than knowledge”.

Chapter 1: Introduction

This chapter contains an introduction to the study, describing software maintenance, why it has become a significant focus of the software engineering discipline and, further, how this focus had led to an increased awareness of flexibility as an important design goal. The aims of the study are itemised, and the research questions are stated.

1.1 Background to the study

Contemporary organisations desiring to remain competitive must review the pace and manner in which they conduct day-to-day business. Increasingly, as Callon (1996, p.106) reports, they rely upon Information Technology (IT) to adapt to the rapidity of change at large and to maintain competitive advantage.

Furthermore, as found by Hall & Ligezinski, (1997a, p.1), the costs underlying provision of IT services are now coming under renewed scrutiny. This is especially true where contemporary development environments are faced with the dual problems of increasing IT resource costs and tighter fiscal management trends.

Maintenance of software brings an ever-increasing cost to a typical organisation’s IT budget. Organisations are reluctant to release exact figures, but Pressman (1997 p.762), cites trends that show a steady increase in such costs from thirty five percent of the total project budget in the 1970s to sixty percent in the 1980s. Pressman’s observed trends are acknowledged by McCracken (cited in Pressman, 1997, p.762),
whose studies indicate that if the trend of increasing maintenance cost continued, as identified in the 1980s, then organisations may become ‘maintenance bound’.

An organisation is described as ‘maintenance bound’ where it is so buried in maintenance that there are no available resources to assign to new projects (Pressman, 1997, p.762). The author suggests that with today’s phenomenon where entire IT organisations consist of employees principally occupied by maintenance of existing software systems, McCracken’s ‘future’ may have become the reality.

Pressman’s (1997) supposition is re-enforced by the findings of Hall and Ligezinski (1997a, p.2), who estimate the cost of software maintenance as being between sixty and seventy percent of an organisation’s total software development budget.

The cost of maintenance may be understood better through the decomposition of maintenance into three main categories as described by Swanson (cited in Pressman, 1997, p.763):

- **Corrective Maintenance**: the identification and correction of software errors, commonly known as ‘bug fixing’.
- **Adaptive Maintenance**: modification of existing software to conform to changing requirements.
- **Perfective Maintenance**: adds new capabilities, modifies existing functions.
The survey conducted by Lientz and Swanson (1980), who sampled 487 members of the Data Processing Managers Association, revealed a distribution of the above categories, illustrated in figure 1:

![Figure 1. Distribution of Maintenance Effort (Lientz & Swanson, 1980)](image)

Figure 1 illustrates that the largest combined portion of maintenance effort, and thus spending, is a result of adaptive and perfective maintenance. Inspection suggests that any effort in improving the maintainability of a system should focus on the perfective and adaptive areas.

![Figure 2. Distribution of Maintenance Activities (Stacey, 1995, p.1)](image)
It may be seen that the trend has not altered significantly in recent times, with a study conducted by Stacey (1995, p.1) showing a similar breakdown, illustrated in Figure 2, in the focus of maintenance activities.

The above studies into the distribution of maintenance activities measure the relative effort of performing the maintenance activities and focus on the visible cost. However, according to Stacey (cited in O'Connor, 1999, p.6) the “hidden costs of maintenance can be even greater” due to:

- Loss or postponement of development opportunities.
- Customer dissatisfaction at not having their needs met.
- Reduction in software quality due to maintenance introduced errors.

By example, Woolfolk, Ligezinski and Johnson (1996, p.482) cite the case of an unnamed American factory where management had decided to increase the efficiency of the organisation by removing middle management and altering the departmental structure. Within six to eight weeks most of the effected personnel had adapted to the changes in procedures and formed new communication lines and work practices. However, Woolfolk et al (1996, p.483) observed that, after a year the “computer systems were only 90 percent complete at a cost exceeding a quarter of a million dollars”.
The literature offers two significant approaches, namely, the employment of flexible software, and that of end user development, to combat the trend of increasing maintenance costs. Each of these will now be introduced.

End user development permits end users to assume the role of developers, thereby taking full responsibility for the creation of their own applications (Mehandjiev & Bottaci, 1998, p.3). Not everyone, however, sees end user development as a panacea. Panko (1998, p.16) found wide criticism for it in the software community due to an increased likelihood of errors derived from informal methods wanting of the rigour known to be necessary in programming. Such rigour, however, may be achieved within professionally developed systems that are designed to incorporate flexibility during use.

Mehandjiev and Bottaci (1996, p.432) see flexible software as helping to bridge the gap between developers and advanced users by allowing the latter to access features that control and modify the behaviour of a system. Likewise, O'Connor (1999, p.7) suggests that “flexible software can be seen as the middle ground between professional IT staff maintained systems and end user development”. Through the use of flexible software, Mehandjiev and Bottaci foresee an advantage, over conventional system development methods, for organisations to adapt applications rapidly to changing requirements.
Woolfolk, Ligezinski & Johnson (1996, p.486) propose that flexible systems fall into one of three categories of flexibility with respect to adaptive maintenance:

- **Weak flexibility**: requires modification to the underlying data structures (e.g. entities and/or tables).
- **Medium flexibility**: requires modification to both data values and procedural code.
- **Strong flexibility**: where data value modifications alone are required.

The author suggests that strong flexibility, appropriate to the needs of contemporary organisations, may be achieved by integrating flexible principles into the underlying database design of an application. Such flexibility may then help to facilitate a cost reduction in both time and effort of eventual maintenance, especially in the activities of perfective and adaptive maintenance. The savings to be gained from flexible development might, reasonably, permit funds to be allocated towards new developments and decrease the risk of an organisation becoming 'maintenance bound'.

### 1.2 Significance of the Study

The relative cost of implementing change in a non-flexible system, illustrated in figure 3, is greatly increased during each phase of the software development lifecycle. It is, therefore, important to focus on the provision of flexibility as part of the requirements capture/analysis phase of a project, in order to mitigate increased development costs resulting from a lack of such focus. The need for such early provision is reinforced by Weinberg (1990), whose study demonstrated the inclusion
of maintainability as a part of requirements capture led to an increased awareness of maintenance issues throughout an entire project lifecycle.

![Figure 3. Relative Cost of Change (Oracle, 2001)](image)

Requirements, as specified by Blum (1993a, p.43), fall into three categories as:

- **Closed**: defined and stable requirements.
- **Abstract**: requirements that have no ‘concrete’ representation, but which incorporate products necessary for development of the system. Primary examples of abstract requirements are ‘security’ and ‘user friendliness’.
- **Open**: requirements where the problem domain is flexible. A flexible problem domain suggests that requirements may lack definition, or change, either during development or post-implementation.

It is the flexibility, or changeability, of ‘open’ requirements that flexible software techniques aim to address. However, as O’Connor (1999, p.9) notes, most applications are specified from requirements observed in all three, not from just one, of Blum’s categories.
Many static systems, i.e. systems without in-built flexibility, are based on fixed requirements and use a traditional ‘sign off’ approach to validate the satisfaction of requirements. Frequently, though, difficulties in specification lie in that requirements, true at the time of the original specification change/evolve, exhibiting the phenomenon known as ‘requirements creep’. To formalise the remedy, Behforooz & Hudson (1996, p.396) state that “maintainability should be specified and software should provide for the highest level of flexibility and ease of maintenance”, giving the following reasons:

- Software maintenance is expensive.
- The advantages of including maintenance as a design goal far outweigh the costs.
- A system may spend between 65 and 80 percent of its life in maintenance.

Others endorse the difficulty of specifying requirements fully, as Woolfolk, Ligezinski & Johnson (1996, p.482) observed that such specifications are “imperfect since a significant part of such requirements lie in the future”. Poor specification, in response to requirements creep may, in turn, “lead to systems that are judged unsatisfactory or unacceptable by the client and have high maintenance costs” (Hofmann, Pfeifer & Vinkhuyzen, 1993, p.43).

While studies, such as the Object Database Management Group’s (ODMG) research into improved methods for requirements capture (“ODMG 2.0”, 1998), software maintenance continues to be an area neglected in the systems development lifecycle. Such neglect is especially noticeable when maintenance phase support is compared to
that of other phases of the software lifecycle. As pointed out by Liu, Yang & Zedan (1998, p.1) “the approaches/tools of maintenance are rather weak when contrasted to those of development”. Liu, Yang & Zedan further suggest the underlying reason for the neglect is that software development is a mature process while maintenance is still viewed as being a difficult and expensive area.

Acknowledging the neglect in maintenance related studies, this study aims to demonstrate that existing static data requirement modelling techniques may be adapted to facilitate a reduction in maintenance effort though the inclusion of underlying flexibility. Outcomes of the study offer systems analysts and programmers a number of potential advantages:

- A flexible method of capturing data.
- A need to learn few (potentially zero) new symbols and/or notations.
- A minimisation of the effort involved in capture of flexible requirements.

1.3 Purpose of the Study

The previous sections indicated that there is credible support in the literature for flexibility as a design goal. However, as shall be shown, there is little clear statement in the literature on how this flexibility may be integrated into either the resultant application or, more importantly, the design model. The purpose of this study is to demonstrate how flexibility may be incorporated successfully into a ‘live’ system i.e. one that may exhibit Blum’s “open” or flexible requirements.

While flexible systems are not new, previous research (O’Connor, 1999; Layng, 1998) has focused on the adaptation of an application around a static data model. The
employment of a static data model has meant that while applications may exhibit features of a flexible system in the user interface (the so-called ‘front end’), the type and volume of stored information (the so-called ‘back end’) remains static. The author proposes that development with a data model that exhibits a measure of intrinsic back end flexibility is an appropriate alternative.

The study focuses on the flexibility of data in the ‘back end’ of an application, making it appropriate to choose a contemporary data-oriented implementation language such as the Oracle 4GL. Additionally, selection of Oracle’s 4GL allows comparison with studies of business-rule oriented front-end flexibility in that development environment, such as those conducted by Hall & Ligezinski (1997a), O’Connor (1999) and Layng (1998).

To summarise, the purpose of this study is to investigate the implementation of a dynamic system using the Oracle 4GL to provide flexibility in the ‘front end’ in conjunction with dynamic mapping to the underlying database ‘back end’.
1.4 Research Questions

The main question:

"How may the challenge of dynamic/flexible user requirements be met using data driven techniques using a contemporary 4GL-database environment?"

The major components of the above question are:

a) "How may one model dynamic user requirements through an extension of current data modelling techniques?"

b) "How may one implement user requirements of flexibility using data driven techniques in a contemporary 4GL environment?"

1.5 Summary

The rising cost of maintenance is an issue that has enjoyed little research effort when compared to other, better-established, phases of the software development lifecycle. While previous studies have indicated the need for corrective action, no notable progress has been achieved towards the realisation of improvements. This study demonstrates that, through an extension of existing techniques, a standard 4GL may be used to implement flexibility in both the ‘front end’ and ‘back end’ of an application.

Chapter two provides a review of the relevant literature. The review draws upon previous work, in textbooks, documented research papers and articles, to provide guidance and justification for the study’s approach of adaptation/enhancement of existing modelling techniques. To further the study’s implementation, existing
techniques that provide flexibility within an application are explored. Finally, documented features of the Oracle 4GL environment that facilitate system flexibility are identified.

Chapter three describes the research design. The methodology undertaken to answer the research questions proposed in chapter one is described, together with the Oracle environment employed to develop the demonstration application.

Chapter four outlines the flexible software techniques implemented using native Oracle features (to be introduced in chapter two), and details the usage of the demonstration application.

Chapter five presents the results and findings of the demonstration application. The findings are discussed in relation to the initial research criteria and compared to previous studies that were discussed in chapter two.

Chapter six concludes the study. A summary is given of the initial aims of the study and the manner in which they were addressed. Finally, the implications of the results and findings are discussed with respect to their benefits to current practice and to future research into flexible software.

This document concludes with a glossary of terms, followed by the end text references for documents used to support the study, and several appendices, which are
used to provide clarification and amplification of significant areas of the study: namely,

Appendix A consists of the data collection form used by the manual submission system (the system is detailed in chapter three);

Appendix B presents the category hierarchy with the required field configurations (the category hierarchy is detailed in chapter three);

Appendix C lists the database creation SQL scripts (the database is introduced in chapter three and detailed in chapter four);

Appendix D illustrates the PL/SQL code used in the Update Layout procedure (the Update Layout procedure is detailed in chapter four);

Appendix E consists of screen captures of the demonstration application’s static data entry screens (the static data entry screens are covered in chapter four); and

Appendix F demonstrates reports generated by the application using the full sample data provided).
Chapter 2: Review of the Literature

2.1 General Literature

Early attempts at flexible systems, such as that proposed by Parnas (1979, p.128) involved designs based on components. Parnas (1979, p.128) suggested a methodology wherein a project commenced with the identification of minimal subsets, each of which might perform a useful service, and then progressed with the addition of minimal increments to the system. Parnas' chosen components conformed to the following general rules:

- Each component should perform a single function.
- A component should not be reliant on the format and output of data from another component.
- Components should not assume that any functionality exists already in the system.

The component-based methodology, such as proposed by Parnas, was gradually replaced in the late 1980s by an object-oriented (O-O) approach to systems development.

Booch (1994, p.37) suggests that flexibility may be achieved through the use of the O-O approach to define a system as a collection of objects rather than components. In the O-O approach a measure of flexibility is achieved through the use of the native object features such as inheritance, abstraction and polymorphism. These O-O features allow a programmer to import previously created classes from standard
libraries, and extend/adapt or overload elements of them without requiring any changes to be made to the original class. In order to obtain maximum synergy between the features of O-O, Booch (1994, p57) states: “modules should be cohesive (by grouping logically related abstractions) and loosely coupled (by minimising the dependencies among modules)”. While the O-O technique does permit inclusion of flexibility in its design, and provides an ability to approach a system definition in iterative and incremental fashion, it is, arguably, not a suitable modelling environment for poorly defined systems that suffer major requirements creep during the maintenance phase.

A fragment-based specification method is presented by Blum (1993b, p.728) to allow a conceptual model to be created for systems where requirements are inclined to be dynamic or poorly understood. Blum’s (1993b, p.730) ‘fragment-based’ method stores concepts, known about the application, as fragments in a database. In Blum’s method, specification fragments are assembled to form a definition of the software functions utilised in code generation for the application. However, whilst Blum (1993b, p.731) advocates the use of methods that allow the gathering of ‘open requirements’, he provides criticism in that “there are high risks in developing systems with open requirements: the resulting product may not be useful”.

Ensor and Stevenson (1997, p.503) propose the implementation of flexibility via user extensibility. User extensibility refers to systems that allow a user to modify a system from within the application, thereby maximising the utility of a system. Ensor and Stevenson (1997, p.504) divide their proposal into two types of flexibility: namely
‘schema extensibility’ and ‘algorithmic extensibility’, in order to classify better those systems with ‘open requirements’. To elaborate, ‘schema extensibility’ refers to situations where new attributes and/or entities are required. ‘Algorithmic extensibility’, then, refers to the changing of the underlying business rules in order to supplement, update or replace the current rules. Ensor and Stevenson advise that where a rule is likely to change, the code used to implement the rule should be stored as a package in a database table, allowing for the easy manipulation of existing rules. The flexibility achieved through the use of these database packages may be extended through the storage of every atomic action (a fundamental, indivisible code element) as a procedure or function in the database, thereby maximising the amount of code reuse and, in-turn, decreasing maintenance costs.

Woolfolk, Ligezinski & Johnson (1996, p.3) put forth the idea of a ‘dynamic search condition’ as a method to implement ‘algorithmic extensibility’. The ‘dynamic search condition’ is used to allow the association of business rules together with data, thus providing both user extensibility and system flexibility. By way of mechanism, such association is achieved through the use of two files and a search program, where the first file contains the data and the second file contains the key values needed to search the data. The search program, illustrated in figure 4, accepts predefined arguments and then searches the data file according to a pattern determined by a key that is built from the key values in the second file. The effect of the mechanism is to allow the program to change the access rules to a table (notably without any modification to the program), effectively providing a facility for changes in business rules applied to the data.
Mehandjiev & Bottaci (1996, p.450) observe that a purely graphical language might provide a level of flexibility not achievable with standard ‘algorithmic extensibility’. Layng (1998, p.16) states: “if an application can be written in a language that is purely graphical rather than text based then there is a huge potential for users to modify the structure of the program as they wish”. However, as yet no ‘pure graphical’ language of any note has been developed that may be applied to the general domain, although the Object Management Group, through their development of Unified Modelling Language (UML), is making advances in this area (Pohl, 1997, p.142).
In order to provide a standard for extensible systems, graphical or otherwise, Hall & Ligezinski (1997b, p.6) suggest four main areas to be addressed by any system before it may be considered flexible:

- **Access security**: where each user needs to access only that functionality for which they have authorisation.

- **Dynamic report formulation**: where reports produced by the system must be able to adapt to changes in the system.

- **Data entry processes**: where data entry screens should not be fixed, as they define the way a user ‘sees’ and interacts with a system.

- **Business rules applying for specific conditions**: where flexible application of business rules is allowed under certain circumstances.

### 2.2 Specific Studies Similar to the Current Study

A method proposed by Hall & Ligezinski (1997b, p.7) to satisfy their four nominated areas of flexibility, is via the use of ‘common code’ tables that allow both specification and implementation of flexible software. They state: “When a new code value needs to be added, or modified, it can be accessed at runtime through database queries, dynamic record groups and lists of values as opposed to the usual predefined pop-lists”. Common code tables, in which values, located on a one to one basis against identifiers known to the program, are read by a program at run time and, therefore, stored ready to be queried immediately prior to use. An example of such use may be to store values for display in screen menus, where the contents of the menus change according to context.
For example, a table called FRUITS might be used in a system to store the name of a fruit and its associated value, and this table may, in turn, be linked via a record group (explained in depth later) for display in a ‘front end’ object or selection list/menu. Thus if a fruit is added to the ‘common code’ table FRUITS the value would automatically be linked with its associated object, e.g. facilitating easy changes to menu contents by editing the FRUITS table contents.

The technique has been used in many recent large systems programmed in Oracle Forms. One such system is the CONCEPT Human Resource Management software, which uses such a ‘common code’ table nominated, appropriately, CODES (illustrated in figure 5), to store codes together with their designated values and descriptions for the entire system. By example, the CONCEPT system exemplifies a useful extension of flexibility to the standard ‘common code’ technique through the ‘kind’ column in the CODES table. Values in the CODES tables are grouped by what ‘kind’ they belong to, and, in turn, the kind determines a link, or indirection, to a specific object to be accessed at runtime. Through this extension CONCEPT is able to store the ‘common codes’ for the entire application in the one table.

<table>

<td>VARCHAR2 (50)</td>
</tr>
<tr>
<td>LENGTH</td>
<td></td>
<td>NUMBER</td>
</tr>
</tbody>
</table>

Figure 5. SQL Description of Concept HR codes tables (Courtesy of Concept Systems)
O’Connor suggests an alternative use for ‘common tables’ to provide a high level of flexibility. The ‘front end’ tables are used to store a large portion of the setup of the ‘front end’ of an application. O’Connor (1999, p.36) provides an example where the ‘front end’ screens of an application are stored in five tables (illustrated in figure 6):

- **ST_FORM**: Stores the names and characteristics of those forms that are present in the system, including such details as the width and height of the form that will be displayed at run-time.

- **ST_ITEM_TYPE**: Stores the names of all item types that may appear on any given form. These include buttons, text items, Lists of Values (LOVs) and radio-button groupings.

- **ST_ITEM**: Stores the names of all possible items that may be included on any form.

- **ST_FORM_ITEM**: Stores the items that will appear on a particular form and indicates how the various different run-time properties (e.g. position, width, and font) will be set when that form is run.

- **ST_FORM_REF**: Stores the names of items that should be displayed on a form based upon values stored in a different table, (e.g. where items are displayed on a Customer maintenance form according to a group to which they belong).
The ‘setup’ tables shown in figure 6 are mapped onto the overall application database according to the Entity-Relationship (E-R) diagram depicted in figure 7. Each form is then defined by altering the defined setup values in a maintenance form, so that when a window is first displayed a call is made to an appropriate function to display the required items. O’Connor (1999, p.56) notes about his design: “the dynamic screen concept appeared a good idea in theory, however it does have many limitations in practice”. The limitations mentioned in O’Connor’s study stem from the increased overhead of querying all five setup tables (shown in figure 6) prior to loading each screen during the application’s runtime.
While the above studies (O'Connor, 1999; Hall & Ligezinski, 1997b) demonstrate techniques utilised successfully to provide flexible systems, they do limit flexibility in the type of data stored. The 'common code' and 'front end' table techniques are limited as they achieve user extensible systems exclusively through the implementation of algorithmic extensibility, ignoring schema extensibility. The study proposes to address this limitation through a dynamic data model (explained in chapter four), providing a level of flexibility superior to the techniques previously described.
2.3 Other Literature of Significance to this Study

Recall that the aim of this study is to provide a system with schema extensibility through an extension of existing techniques. Inevitably, such extension includes the rules governing normalisation, modelling of data, and specific techniques for the implementation of native features that promote or facilitate flexibility in environments such as Oracle. A modelling method that complements normalisation, and that will be employed in the study, is that of Entity-Relationship (E-R) modelling, where business rules may be applied and where the completeness of data attributes is not necessarily known at inception of the model. In other words, the tables we use to provide flexibility must be constructed according to the rules of normalisation and E-R modelling that apply to any well-founded database. Both of these techniques will now be elaborated, together with other literature of significance to the study.

2.3.1 Normalisation

Codd (1970, p.378) formulated a mathematically based set of design principles for use in designing relational databases. These principles have become formalised in terms of progressive normalisation of data via, at least, three normal forms (known as: first, second, and third normal form). Other normal forms are now known to exist but will not be covered in this review. Normalisation is, in effect, a data drive, 'bottom-up' approach and its purpose is to remove what are known as the 'three side effects', which are, paraphrased from Beynon-Davies (1996, p.144):

- **Deletion side effect**: where the deletion of a specific piece of data results in the loss of related information that is still valid.

- **Update side effect**: where the operation of updating a single piece of data requires the modification of more than one database column.
• **Insertion side effect:** where data may not be entered as it is dependent on having at least one link to another part of the system.

The removal of the Beynon-Davies’ side effects ensures database stability following volatility of its contained data.

Beynon-Davies (1996, p.145) describes normalisation as consisting of four steps:

1. Collect the data set into a list of un-normalised data.

2. Transform the resultant list into tables in the first normal form: defined by Beynon-Davies (1996, p.147) as:

   “A relation is in first normal form if and only if every non-key attribute is functionally dependent upon the primary key.”

3. Transform first normal form tables to second normal form: defined by Beynon-Davies (1996, p.149) as:

   “A relation is in second normal form if and only if it is in first normal form and every non-key attribute is fully functionally dependent on the primary keys.”

4. Transform second normal form tables to third normal form: defined by Beynon-Davies (1996, p.151) as:

   “A relation is in third normal form if and only if it is in second normal form and every non-key attribute is non-transitively dependent on the primary key.”
Following the above steps produces a stable and efficient relational data model on which an application may be based with confidence. Accordingly, the practice of normalisation is adhered to in this study in order to yield such stability and efficiency of stored data in its example application. Normalisation is also used to analyse and incorporate data storage information into the data set to provide a schema extensible system. This will be explained in chapter four.

2.3.2 Entity Relationship Modelling

To complement the 'bottom-up' approach to database design, i.e. normalisation, a 'top down' analysis, known as Entity-Relationship (E-R) modelling, is generally followed by current practitioners. E-R modelling is employed particularly in situations where an analyst may not know all needed data before modelling commences. It provides a rapid approach for producing a model that may subsequently be refined using normalisation techniques and, as Beynon - Davies, (1996, p.162) reports: "In practice, database developers normally do more data modelling than they do normalisation."

The E-R modelling approach was devised by Chen (1976) to facilitate data modelling for problem areas for which a database solution is envisaged and is used frequently in association with the relational model.

The first step in conducting E-R modelling is the identification of all necessary entities. The exact definition of what constitutes an entity varies, but Beynon - Davies (1996, p.162) provides the following: “An entity may be defined as a thing which the entire enterprise recognises as being capable of an independent existence and which can be uniquely identified”. This definition concurs with that of Hall (1998, p.7) who
defines an entity as "An individual object, concept or event about which the organisation chooses to collect and store data". In E-R models, named rectangular objects depict entities, as shown in figure 8.

To model the interaction/association between entities a relationship is used, depicted an example of which is shown in figure 9. Three relationships are known to exist in Chen's model:

- **One to one relationships**: where an instance of one entity has a direct single link to another separate entity.

- **One to many relationships**: where an instance of one entity has multiple direct links to another separate entity.

- **Many to many relationships**: where many instances of the same entity have links to many instances of another separate entity.
A completed E-R model, in conjunction with the normalised data, shows the structure and detail of an intended database, in which entities are implemented as tables and relationships achieved by linking key attributes common to related tables.
2.3.3 Native Oracle Features used to facilitate flexibility

The Oracle development environment is provided for the creation of the ‘front end’ of an Oracle application. The ‘front end’ facilitates, for the user, an interface to the underlying database ‘back end’. Innate in the Oracle development environment are many features that may be used to enhance and create flexible applications.

O’Connor (1999, p.24) suggests that the most useful of these flexibility enhancing features are:

- %TYPE
- Setting Properties Programmatically
- Dynamic Record Groups
- List of Values

Each of O’Connor’s ‘flexibility features’ will now be elaborated in turn.

2.3.3.1 %TYPE

The identifier %TYPE declares a variable of:

- a previously declared variable
- a column in a table

The %TYPE identifier is utilised in the variable declaration section of Oracle procedures, functions and packages to ensure type consistency. Consider the database table depicted in figure 10 and the PL/SQL procedure block illustrated in figure 11:
In figure 11, the variable Flex_Value is declared from the same type as a value originating in the database column Char_Col in the table Flex shown in figure 10. The full value of using the %TYPE identifier in this manner becomes apparent when used in database side subprograms of procedures, packages and functions. In these database side subprograms, efficacy is achieved as they are automatically recompiled before every runtime. Such recompilation allows the %TYPE to reassign the variable type when required, such as following a change in the underlying type of a database item. Even when the %TYPE is used in client side functions, the type used by the application may be updated by performing a manual re-compile.

The %TYPE feature enhances the flexibility of database procedures and functions by allowing them to adapt to changes in data formats. Stacey (1995, p.3) held such changes accountable for the greatest portion of software maintenance activities.
Stacey’s opinion agrees with that of Feuerstien (1996, p.25) who states that the most common cause of application failure is “the undying belief held by programmers that a particular value will never change and so can be hard coded into the program.” O’Connor (1999, p.27) cites a Ministry of Justice [of Western Australia] case management system that has implemented a change of underlying database types by using the %TYPE feature and subsequent recompilation to activate the changes.

### 2.3.3.2 Setting Properties Programmatically

A property is defined in Oracle (2001) as “an attribute of an item that may altered to modify the setup of that item.” Manipulation of these attributes is achieved via property functions that allow, for example, a facility for manipulation of the physical properties of graphical objects, where the manipulation may result in an enhancement to the flexibility of a system. Development environments such as Oracle’s Developer provide utilities of GET and SET property functions, examples of which include:

- **SET_ITEM_PROPERTY**: Modifies all instances of an item in a block by changing a specified item property.

- **GET_ITEM_PROPERTY**: Returns property values for the specified item.

- **SET_WINDOW_PROPERTY**: Sets a property for the selected window.

- **GET_WINDOW_PROPERTY**: Returns the current setting for the selected window property for a given window.

- **SET_BLOCK_PROPERTY**: Sets the given block characteristic of a specified block.
• **GET BLOCK PROPERTY**: Returns information about a specified block.

Through these standard SET and GET functions it is possible to manipulate the ‘front end’ of an application, thereby allowing a quasi-visual form of flexibility that approximates Mehandjiey & Bottaci’s (1996, p.450) idea of providing flexibility by using a graphical method.

### 2.3.3.3 Dynamic Record Groups

Record groups may be used to provide both query and data flexibility in applications. They form sets/lists of information that may be created and populated through the use of SQL queries. Typically, record groups, are used to generate small subsets of data for those specialised operations where no information update is occurring, e.g. when checking if a value exists. Hall & Ligezinski (1997b, p.7) suggest that dynamic record groups are best employed in conjunction with the previously described common code tables.

A typical example of a record group would be a small SQL query that extracted a list of items, each of which has a common property, from a table e.g. a list of all the male employees in an organisation’s payroll system. The record group might then be used inside an application in preference to a non-record group situation where the same query would have to be run multiple times to achieve the same effect.
2.3.3.4 List of Values

LOVs are a native feature of Oracle and may be used to replace the traditional static lists, known also as ‘pop lists’ or combo-boxes, found in standard application front ends. They are associated directly with a record group, thereby “ensuring the information they contain is always current” (O’Connor, 1999, p.29).

Additionally, unlike ‘pop lists’, a LOV does not require a direct link to a text item, thereby allowing sufficient flexibility to attach a LOV to a button or a menu item. While a LOV may be associated directly with a text item in its property settings, a function such as that depicted, in figure 12, as SHOW_LOV may be used to handle the activation of the LOV programmatically. The SHOW_LOV function has a return type of Boolean, returning TRUE where a value is selected or FALSE if the user cancelled the LOV.

```
DECLARE
    LOV_Used BOOLEAN;
BEGIN
    LOV_Used := SHOW_LOV('A_LOV');
END;
```

Figure 12. Calling a LOV using PL/SQL
2.4 Summary

Employing facts and documented experience, selected literature has been used to provide a basis for a discussion about identifiable, desirable features that may promote development of flexible systems. The concept of flexibility has been discussed with an emergent idea that to provide a strong level of flexibility a system should be alterable through data values that are held in tables, rather than by the use of code. In addition, those inherent features of the ORACLE database language that may be employed to promote and facilitate flexibility in a relational based system were reviewed.
Chapter 3: Research Method

This chapter outlines the methodology followed by the study to provide answers to the research question proposed in chapter one. It also describes the guidelines for the development of the demonstration application that is discussed in chapter four.

3.1 The Problem

In order to address the research question of "How may the challenge of dynamic/flexible user requirements be met using data driven techniques in a 4GL-database environment?" a demonstration application was designed and implemented using the Oracle 4GL environment. The resultant application implements a staff activity submission system and was chosen for the following reasons:

- The 'real-life' requirement for such a system by Edith Cowan University (ECU);
- The unpredictable nature and rapid changes in requirements manifested in the current manual system.

The requirements of the system were gathered in a series of interviews and information/data analysis sessions, the results of which were entered into a CASE tool. A summary of the problem statement is as follows:

On a quarterly basis, the faculty creates the staff newsletter. In order to collect the information for the newsletter, a form (see appendix A) is emailed to all staff members and, ideally, this form is then completed by
staff and emailed back to the newsletter editor. The editor then manually collates and corrects all the information in accordance with the data collection guidelines (see appendix B) and uses this information to create the newsletter.

The following problems were observed with the manual system:

- Difficulty of tracking whether a staff member has/hasn’t submitted a return in a specific quarter.
- Manual collation of returns is very time consuming.
- It is hard to inform staff of changes to the form.
- Returns on the form are often in an inappropriate format.

ECU management, following requests by users, decided to commission a computer-based solution. The replacement system needed to address the following issues:

- Allowing staff to enter/maintain their own returns at any time.
- Allowing updates of categories and their associated return items.
- Providing reports to allow easy data extraction.
- Permitting two levels of access: i.e. standard user and administrator.

An initial analysis, described later in this chapter, of the problem area was utilised as a guide for the design and construction of the demonstration application. The
application's development was then separated into several phases, each of which is introduced in this chapter and, further, discussed in depth in chapter four.

### 3.2 E-R Analysis

The first phase in the design of the demonstration application was an analysis of the problem domain together with the client/user-supplied data. The analysis was used to construct an E-R model and normalised view of the system's data. Recalling that part (a) of the research question was stated: "How may one model dynamic user requirements through an extension of contemporary data modelling techniques?", E-R modelling was used to build a model to demonstrate such extension.

The extension was achieved through an investigative process; wherein the system was modelled initially using standard modelling techniques and normalisation. The standard model was then analysed for weakness, and the identified weaknesses were addressed to facilitate the creation of a dynamic model. This process has been detailed further in chapter four.

### 3.3 Database Design

Upon completion of the E-R analysis the resultant model and normalised data set were converted, using Oracle CASE tools, into a relational database. The successful generation of the database creation scripts from the CASE tool (Appendix C) with the supplied E-R model confirmed the model's validity and provided the 'back end' of the demonstration application.
3.4 Application Development

Development of the demonstration application commenced following the database design phase, in accordance with the requirements gathered therein. Oracle's Developer 6i tool-set was selected for development, for reasons of availability, maintainability and relevance to the task-in-hand, and consists of:

- **Oracle Forms Developer 6i**: A graphical based development language for constructing user interfaces.

- **Oracle Reports Designer 6i**: An SQL based reporting tool used to develop and publish data queries.

- **Oracle SQL 8i**: A structured database query language that contains enhancements over and above the standardised SQL.

Furthermore, the tools, all from the same vendor, ensured maximum coordination between the 'front end' under development and the 'back end' developed during the database design phase. The application was then integrated in an incremental fashion, where each individual form (screen) was developed as a standalone module before being merged into the overall application.

The development and implementation of the demonstration application, in conjunction with the flexible database design, was used to answer part (b) of the research question, stated previously as: "How may one implement user requirements of flexibility using data driven techniques in a contemporary 4GL environment?"
3.5 Oracle Environment

The development and presentation of the Staff Submission System was performed on two network and internet enabled IBM compatible personal computers. One machine acted as a development machine and comprised a Pentium III processor with a clock frequency of 700MHz, memory capacity of 128Mb, and a hard disk drive with 10 Gb of storage. Microsoft Windows NT 4.0 (Service Pack 5) was chosen as the operating system, due to its compatibility with the Oracle software used.

The second machine acted as a client, and was typical of that supplied to a user of the Staff Submission System. The client machine comprised a Pentium III processor with a clock frequency of 600MHz, memory capacity of 64Mb, and a hard disk drive with 8 Gb of storage. Typical, again, of a user’s machine, client applications were hosted by the Microsoft Windows 98 operating system.

The following products were installed on the development machine:

- Personal Oracle Database version 8.1.6
- Oracle Developer 6i
- Oracle Designer 6i

The following products were installed on the client machine:

- Oracle 8i Client Run-time
- Adobe Acrobat Reader
- Internet Explorer 5.01
In short, the environment and development tools were chosen to reflect a standard industry configuration, based upon the technical advice given by several experienced and qualified practitioners and ECU technical support staff.

3.6 Summary

This chapter has introduced the problem statement that the sample application addressed, outlined the development phases of the study, and related them to the respective component of the research question that they were employed to address.

The environment used to implement the study was introduced and discussed. Chapter four elaborates on the phases introduced in this chapter (principally, those of analysis, design, and development) and details the demonstration application.
Chapter 4: The Demonstration Application

This chapter details the development of the demonstration application, nominated the Staff Submission System. The system was developed in accordance with the research method outlined in chapter three, incorporating, where appropriate, the techniques and features reviewed in chapter two.

4.1 The Database

The sample application’s implementation commenced with database construction. In accordance with contemporary design techniques, an incremental process was followed, wherein individual database tables and constraints were modelled and reviewed, in both an initial and flexible design, before being integrated into the database. This allowed for progressive testing and validation of the design whereupon the creation scripts were generated using the CASE tool previously outlined in chapter three. The manner in which the model and resultant database were constructed will now be elaborated.

4.1.1 Initial Design

In order to prevent any neglect/loss of data requirements during the database design, the system was first subjected to straightforward E-R modelling to produce an initial standard model, depicted in figure 13, without consideration of any flexible requirements of the system. This was undertaken in order to identify, subsequently, any possible weaknesses exhibited by the standard model of the system, and to provide a base for development of the flexible model.
Figure 13. Initial ER-Model of system
Upon examination, two problems were identified as being inherent in the standard model illustrated in figure 13: namely,

- a lack of categorisation; and
- an inefficiency of storage of optional data.

Both of these problems are now explained, in turn.

The importance of the categorisation of elements, listed in appendix B, is ignored by the standard model, which relies upon category elements being 'hard coded' into the menu screens of the application. The menu screens would be required to store the correct category information in order to store data in all six of the item tables (i.e. Article, Award, Event, Appointment, Book, and Grant) illustrated in figure 13. The storage via such screens mandates the use of a single field in each item table to store data for the category of which the item is a member. It may be seen that the structure for such hard-coding of the category hierarchy is rigid and, further, that such rigidity may lead, eventually, to increased maintenance costs in the event of revision of the category hierarchy becoming necessary.

A second deficiency of the standard model, illustrated in figure 13, lies in the amount of overhead for optional data to be stored by all six of the item tables. For example, the 'Book' table described in figure 14 contains four columns that are not needed in every situation, but that would appear on related data entry screens.

<td></td>
<td>VARCHAR2(150)</td>
</tr>
</tbody>
</table>

Figure 14. Description of the BOOK table

Both of the identified problems suggest that the standard model exhibits extreme limitations in its ability to allow for ‘schema extensibility’ (discussed in chapter two). By example, should the user wish to enter a new type of item, (e.g. videos) into the category hierarchy to allow a new type of input data, the application would require the following maintenance tasks:

- The addition of a new table to store the data, i.e. a new entity added to figure 13, linked to the ‘Return’ table.

- The creation of, at least, one new screen to allow data entry into the new table.

- The alteration of hard coded category settings to accommodate the new item type and its associated screen(s).
The nature of the maintenance tasks implies that the standard E-R model’s limitations would have a noticeable cost associated with modifications to those hard-coded features required in response to requirement changes.

4.1.2 Flexible Design

To overcome the limitations of the initial, non-flexible, data model the problem area was reviewed in order to effect a reduction of possible future maintenance costs. The increased maintenance imposed by the standard model’s six separate item tables (illustrated in figure 13) was mitigated by the introduction of a single table structure. The single table is capable of storing all of the category hierarchy information that would, in the non-flexible, standard application, be hard coded.

When modelling the category hierarchy the following points were considered:

- Categories may contain one or more subcategories.
- Subcategories consist of one or more data items, e.g. a subcategory storing book details may consist of the following data items: author names, publisher details, date published, and book title.
- A data item may exist in more than one subcategory e.g. one or more subcategories may include ‘name’ as a valid field.
The resultant data model, illustrated in figure 15, permits storage of all the information contained within the category collection list described in appendix B. In addition the 'Composition Rule' entity permits storage of dynamic mapping data allowing application fields to be remapped automatically at runtime.

However, before this dynamic mapping might be added to the 'Composition Rule' entity, a dynamic storage entity was required to provide a suitable data storage area onto which to map the application fields. In order to achieve an optimal form for the dynamic entity, the storage requirements of each return item in appendix B were mapped onto the table shown in Figure 16.

Figure 16. Storage requirements of category items
The table depicted in figure 16 indicates that a dynamic entity, nominated 'Return Item', that contains columns of five character, one memo, one date and one number type may be used to store any category item. To this end, and to allow for future growth, a dynamic entity configured with six characters, one memo, two date and two number columns was implemented. The dynamic entity provided the required bridge between the data model in figure 13 and the category definition data model in figure 15. The resultant, complete, model is illustrated in Figure 17.
The bridge works by defining the configuration of the ‘Return Item’ entity (in figure 17), for each combination of the category hierarchy. The configurations are stored in the composition rules entity and accessed via application scripts whenever data is required to be stored/retrieved from the dynamic entity. Thus each category combination may have its own unique way of viewing the data stored in the dynamic entity of ‘Return Item’.

4.1.3 Creating the database

The resultant system model was entered into the Oracle CASE repository using the E-R modelling tool. The CASE tool was then used to produce the database creation scripts listed in appendix C, whereupon these were run on the database to form the ‘back end’ of the flexible application.

4.2 The Application

The flexible application, consisting of a graphically based ‘front end’, was constructed to sit atop the ‘back end’ database. To facilitate the flexibility, the sample application development was split into three logical areas:

1. The first area was concerned with the setup and maintenance of the flexible area of the application i.e. that of the category tables illustrated in figure 15.

2. The second area contained those standard functions of the system that utilise the setup data from the category tables illustrated in figure 15, to present flexible data entry screens.

3. The third area of the application focussed upon retrievability of the data entered into the flexible system.

Each of the above development areas will now be elaborated.
4.2.1 Flexible Setup

The nature of the flow and connectivity of the system's forms, or screens, is derived from the category setup data. Accordingly, a form flow diagram was constructed, illustrated in figure 18. Each 'box' shown in figure 18 translates directly to one or more functions/forms in the final application.

![Diagram](image)

In order to maintain system integrity, this flow forces the application's users to adhere to both the logical and the physical relationship existent between the category maintenance tables (those illustrated in figure 15). The flow also ensures that the transition of the application forms/screens gives the user an implicit, even intuitive, understanding of the relationship between the setup information and how it is controlled by the system. In order to demonstrate this understanding each of the functions/forms illustrated in figure 18 will be explored in detail.
4.2.1.1 Category Maintenance

The user, through the category maintenance form, illustrated in figure 20, carries out category maintenance. The form provides a graphical interface between the user and the category database table they are altering, described in figure 19.

<table>
<thead>
<tr>
<th>Name</th>

</tr>
<tr>
<td>CAT_DATE_REMOVED</td>
<td></td>
<td>DATE</td>
</tr>
</tbody>
</table>

Figure 19. Description of the CATEGORY table

Figure 20. Category maintenance form
Each category maintenance function is associated with one of the five buttons on the form, shown in figure 20. When a button is selected, one of the following operations is activated:

- **Previous**: To navigate to the preceding category information, and where no preceding category exists then this button appears disabled.
- **Back**: To close the category maintenance form, and return to the main menu.
- **Next**: To navigate to the succeeding category information; and where no succeeding category exists then this button becomes disabled.
- **Remove**: To set the removal date to today's date, having the effect of removing this category from the category hierarchy. Furthermore, this button will raise an error message if the currently selected category contains any open subcategories.
- **Drill Down**: To open the subcategory maintenance form described in the next section.

These operations permit the user to maintain the data stored in the category table with minimal effort.

### 4.2.1.2 Subcategory Maintenance

In similar style to the category maintenance functions, subcategory maintenance functions focus on the maintenance of a specific table, in this case the subcategory table, nominated SUB_CATEGORY, described in figure 21. However, there is an extra level of complexity involved in the maintenance of a subcategory due to its
breakdown into further subcategories (in effect, sub subcategories). Three forms, illustrated in figures 23 to 26, were developed to achieve sub-category maintenance, the flow and hierarchy of which is depicted in figure 22.

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAT_NO</td>
<td>NOT NULL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>SUB_CAT_NO</td>
<td>NOT NULL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>SUB_SUB_CAT_NO</td>
<td>NOT NULL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>SUB_CAT_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2{50}</td>
</tr>
<tr>
<td>SUB_CAT_DESCRIPTION</td>
<td>LONG</td>
<td></td>
</tr>
<tr>
<td>SC_DATE CREATED</td>
<td>NOT NULL</td>
<td>DATE</td>
</tr>
<tr>
<td>SC_DATE REMOVED</td>
<td>DATE</td>
<td></td>
</tr>
</tbody>
</table>

Figure 21. Description of the SUB_CATEGORY table

The entry point of the subcategory maintenance flow is via a 'Subcategory Ownership' form, illustrated in figure 23. This form, which is called from the previously discussed 'drill down' button on the category maintenance form (figure 20), displays a list of the subcategories relating to the category selected in the calling
form. The form’s purpose is to allow the user to see an overview of the category-subcategory hierarchy.

Figure 23. Subcategory ownership form

The purpose of each of the four buttons on the ‘Subcategory ownership’ form, figure 23, is as follows:

- **Add Sub Category**: To Open the ‘Add Subcategory’ form (figure 24) for the input of a new subcategory.

- **Add Sub Sub Category**: To open the ‘Add Subcategory’ (figure 25) form for the input of a new sub subcategory.

- **View Details**: To open the ‘View Subcategory Details’ (figure 26) form and display the details for the selected subcategory.
• **Back:** To close the ‘Subcategory ownership’ form, and return to the category maintenance form.

Providing addition of subcategories, a variant of the ‘Add Subcategory’ form is called according to whether the ‘Add subcategory’ button or the ‘Add sub sub category’ button is pressed on the ‘Subcategory ownership’ form (figure 23). The two variants are shown in figures 24, for editing Subcategories, and figure 25, which has an additional field necessary for adding Sub Sub Categories.

![Figure 24. Add subcategory form (format 1)](image)

Figure 24. Add subcategory form (format 1)
In order to edit either sub or sub-sub categories, thus completing the flow depicted in figure 22, an appropriate variant of the ‘View subcategory details’ form is provided. These are illustrated in figure 26 and 27. The buttons at base of these forms provide the following functionality:

- **Remove**: Sets the ‘date removed’ field to today’s date, which has the effect of removing the subcategory from active use.

- **View Rules**: Calls the ‘composition rules’ form, which, in turn displays the setup rules of the current subcategory.

- **Back**: Closes the current form and returns control to the previously mentioned ‘Subcategory ownership’ form.
Figure 26. View subcategory details form (format 1)

Figure 27. View subcategory details form (format 2)
4.2.1.3 Composition Rule Maintenance

Composition rule maintenance activities represent the final stage in the category maintenance flow (figure 18). They provide a means by which the user may control dynamic properties of the system and are facilitated by using the composition rules maintenance form illustrated in figure 28.

![Composition Rule Maintenance Form](image)

Recall the discussion in section 4.1.2, wherein a bridge was created to facilitate the mapping of configuration rules that determine how the dynamic table, 'Return Items', will be accessed. The rules are setup/maintained via the 'Composition rules maintenance' form (figure 28). In addition, the form is used for configuring the on-screen layout of the main data entry screen, which will be discussed in the next section.
The columns in the composition rules maintenance form each control an individual link of the dynamic mapping process via the following functionality:

- **Prompt**: The label used to describe the data stored in its associated column e.g. a prompt value of ‘Name’ would result in a field called Name being displayed on the dynamic data entry screen and in the flexible reports.

- **Column**: The number of the database column to be mapped to, in accordance with the column-mapping table illustrated in figure 29.

<table>
<thead>

<tr>
<td>10</td>
<td>DATE_TEN</td>
<td>DATE</td>
</tr>
<tr>
<td>11</td>
<td>DATE_ELEVEN</td>
<td>DATE</td>
</tr>
</tbody>
</table>

*Figure 29. Column mapping table*

- **Type**: This field is automatically updated, based upon the database column number in the previous field, as shown in figure 29.

- **Sequence**: This field determines the order in which the defined fields will be displayed in both dynamic screens and reports. Alteration of this value facilitates immediate change of all related screen layouts.
Thus, through the ‘Composition rules maintenance’ form the user may define the rules governing access to the dynamic table, ‘Return Item’ and, further, how an individual display item will be seen by other users of the system during data entry.

4.2.2 Data Entry

Recall, as discussed in section 4.2, the second phase in the development of the application is concerned with data entry. The data entry functions of the Staff Submission System are separated into two further sections:

1. Those functions relating to the dynamic features of the database; and

2. Those functions relating to the static features of the database.

Each of the above data entry areas will now be elaborated.

4.2.2.1 Dynamic Data Entry

The functions controlling dynamic data entry relate to the process by which a staff member (user) creates and edits return items. As with the category maintenance process (discussed in the previous section), development of the staff return entry process was initiated by creation of the form flow diagram illustrated in figure 30.
Figure 30 models the logical flow for the entry/maintenance of return items, beginning with selection of a collection period deriving from the need (detailed in the problem statement stated in chapter three), for staff to submit a return every quarter. Selection of a collection period was facilitated in the data model by the definition and storage of the quarterly return dates inside the table nominated 'Collection Period' (figure 17). A link is provided between a staff member and a collection period, in the 'Staff Return' table described in figure 31, allowing the system to log the date of submission and the collection period of a return item.

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>

<td>NOT NULL</td>
<td>VARCHAR2 (8)</td>
</tr>
<tr>
<td>COLLECT_NO</td>
<td>NOT NULL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>RETURN_DATE</td>
<td>NOT NULL</td>
<td>DATE</td>
</tr>
</tbody>
</table>

Figure 31. Description of the STAFF_RETURN
With this functionality in mind, the ‘Choose Collection Period’ form, illustrated in figure 32, was developed, wherein a user may choose between viewing a previously submitted return and the submission of a new return.

![Choose Collection Period form](image)

**Figure 32. Choose Collection Period form**

The functionality of each of the buttons on the ‘Choose Collection Period’ form, figure 32, is as follows:

- **Back to Main Menu**: To close the ‘Choose Collection Period’ form, and return to the main menu.

- **New Return**: To open a LOV containing a list of all collection periods that a staff member hasn’t submitted a return for, and, in consequence, to add the selected period to the ‘Choose Collection Period’ form data.
• **View Return**: To open an existing return related to the adjacent collection period in the ‘View Return Items’ form described below.

Following development of the ‘Choose Collection Period’ form, it became necessary to create a method of viewing submitted return items. Functionality for this was provided by a ‘view return items’ form, which facilitated the addition/maintenance of return items. Recall that the rules defining access to the ‘Return Items’ table are defined by the configuration rules maintained by the composition rule maintenance functions (discussed in Section 4.2.1.3). The ‘View Return Items’ form provided a focus for the translation the configuration rules into an aesthetically functional format.

</tbody>
</table>

62
The placement of all columns of the ‘Return Item’ table, illustrated in figure 34, onto the ‘View Return Items’ form enabled the form to be altered physically at runtime through the use of ‘GET’ and ‘SET’ property functions. Recall that the general applicability of these functions was reviewed in section 2.3.3.2, whilst their applicability specific to this component of the study will now be elaborated.

The ‘GET’ and ‘SET’ property functions were utilised in a procedure named ‘update layout’, presented in pseudo code in figure 35 and listed in appendix D. The ‘update layout’ procedure uses the category details of the current item to access the user-defined rules stored in the ‘Composition Rules’ table, described in section 4.2.1.3. The configuration rules are used to restrict the fields that may be displayed, to establish the labels next to each of those fields, and to determine the order in which the fields appear.
BEGIN
    GET CURRENT CATEGORY VALUES
    IF USER IS ADMINISTRATOR
        SHOW DISPLAY_IN_REPORTS FIELD
    ELSE
        HIDE DISPLAY_IN_REPORTS FIELD
    END IF

    FOR EACH COLUMN IN THE RETURN_ITEMS TABLE
        SET ITEM_NAME TO CURRENT ITEM
        CHECK COMPOSITION_RULE DATA ON ITEM
        IF COLUMN IS NOT NEEDED
            HIDE THE ITEM
        ELSE
            SHOW THE ITEM
            DISPLAY RELATED ITEM PROMPT
            POSITION ITEM ON SCREEN
        END IF
    END LOOP
END

Figure 35. Update Layout pseudo code

As the format of the display may have changed since its last invocation, selection of any of the ‘Next’, ‘Previous’, ‘Add’, and ‘Delete’ buttons triggers the procedure ‘update layout’ following standard Oracle navigation features, so that the contents of the ‘View Return Items’ screen are consistent with the form’s underlying configuration data. In addition, selection of the ‘Add’ button will invoke a ‘Choose Category’ form, depicted in figure 36, to allow a user to select a return type from a list of categories, sub categories and if necessary, sub sub categories.
The 'Choose Category' form, illustrated in figure 36, consists of three text boxes and their associated selection buttons. Each selection button is related through its internal properties to a LOY that enables the display a list of available categories, sub categories or sub sub categories. The list displayed is determined by the point of entry within the hierarchy implied in the data model shown in figure 15, i.e. the LOV showing sub categories is limited based on the previously selected category value demonstrated in figures 37 and 39.

Each of the LOVs are based upon dynamic record groups that are re-queried each time the LOV is called, ensuring the list provided is always up to date as discussed in section 2.3.3.3. The queries behind the category and subcategory record groups are illustrated in figures 38 and 40. Figures 38 and 40 are positioned adjacent to their respective LOVs in figures 37 and 39.
SELECT ALL CATEGORY.CAT_NO, CATEGORY.CAT_NAME
FROM CATEGORY
WHERE ((CATEGORY.CAT_DATE_REMOVED IS NULL)
OR CATEGORY.CAT_DATE_REMOVED <= SYSDATE

Figure 38. Choose Category Record Group
SELECT ALL SUB_CATEGORIES.SUB_CAT_NO,
       SUB_CATEGORIES.SUB_CAT_NAME
FROM SUB_CATEGORIES
WHERE SUB_CATEGORIES.CAT_NO = :CHOOSE_ITEM_TYPE.CAT_NO
AND SUB_CATEGORIES.SUB_SUB_CAT_NO = 0
AND ((SUB_CATEGORIES.SC_DATE_REMOVED IS NULL) OR
     (SUB_CATEGORIES.SC_DATE_REMOVED >= SYSDATE))
AND (SUB_CATEGORIES.SC_DATE_CREATED <= (SYSDATE))

After a valid category/sub category combination has been selected on the 'Choose Category' form the 'Accept' button may be pressed, whereupon the selected category values are passed to the 'View Return Items' form in readiness to display the new data item. In addition, the 'View Return Items' form calls the 'update layout' procedure (whose pseudo-code is outlined in figure 35), thereby reconfiguring its layout to the format dictated by the data contained in the 'Composition Rules' table.
By example, two sample displays of dynamically configured ‘View Return Items’ forms are illustrated in figures 41 and 42. It is important to acknowledge that the setup of these two forms is entirely dependent upon the configuration rules entered via forms within the category maintenance flow (figure 18).
The flow between the 'Choose Collection Period', 'View Return Items', and 'Choose Category' flexible data entry form enables the user to view or alter any type of item previously defined in the category maintenance screens. Notably, these flexible data entry forms interface with the system's static data entry forms seamlessly, hiding their underlying complexity from users of the system. The static data entry forms are outlined in the following section.

4.2.2.2 Static Data Entry

The remaining data entry forms are focused on the static part of the database illustrated in figure 17. The flow of static forms is shown in figure 43. The forms have no flexible content; accessing directly the current values of underlying database fields associated with displayed fields and, further, were developed with standard Oracle features. In short, they do not contribute to the enhancements demonstrated in the study. Accordingly, for the purpose of clarity only, they will be outlined briefly below.
The system’s static data entry forms display data derived, in standard format, from databases external the Staff Submission System, and facilitate the following functionality, the flow of which is illustrated in figure 43:

- **Personal Details**: To add/alter data in the ‘STAFF’ table.
- **Change Password**: To change a user’s password.
- **Discipline Memberships**: To add/alter the Discipline Areas of which a user is a member.
- **Research Memberships**: To add/alter the Research Groups of which a user is a member.

Examples of the appearance of each of these forms are contained within appendix E. They were removed to an appendix, as they do not form part of the study’s focus and to maintain brevity within the main document and, for the benefit of the reader.
4.2.3 Reporting

The third area of the application, identified in section 4.2, is occupied with querying and reporting of data in the database. The reporting functions use the same configuration rules as the ‘View Return Items’ form (outlined in section 4.2.2.1), thereby fulfilling the requirement that they: “allow easy data extraction” identified in the statement of the problem in section 3.1.

The reporting requirement was satisfied by provision of nine reports, each developed to provide a wide range of data extraction options. In brief, the purpose of each of the reports is as follows:

- **Individual Return**: To report a complete listing of all return items submitted by an individual within a specific collection period.

- **Period Report**: To report all return items submitted within a specific collection period.

- **Specific Category**: To report all return items of a specific category, submitted within a specific collection period.

- **Rules**: To report the current configuration rules contained in the category maintenance tables (figure 15).

- **No Return**: To report names and contact details of those staff who did not submit a return within a specific collection period.

- **Discipline Membership**: To report a list of staff members who belong to a specific discipline.
- **Research Membership**: To report a list of staff members belonging to a specific research group.

- **Individual Membership**: To report the disciplines and research groups to which an individual staff member belongs.

- **Staff in System**: To report a list of details for staff as stored in the database.

The flexible nature of the database necessitated the development of a SQL query akin to the ‘update layout’ procedure (represented in figure 35) so that standard Oracle Reports software might present the correct layout for each data item. The resultant SQL query, described in figure 44, followed the indirection defined by the contents of composition rules table, replicating the flexibility employed to configure the ‘View Return Items’ form (outlined in section 4.2.2.1). In other words, as will be shown in following paragraphs, the same configuration rules established for flexible user screens are employed to provide flexible system reports, thereby achieving a doubling of the rules’ efficacy.
SELECT
  STAFF_RETURN_ITEMS.STAFF_NO,
  STAFF_RETURN_ITEMS.line_NO,
  STAFF_RETURN_ITEMS.COLLECT_NO,
  STAFF_RETURN_ITEMS.CAT_NO,
  STAFF_RETURN_ITEMS.SUB_CAT_NO,
  STAFF_RETURN_ITEMS.SUB_SUB_CAT_NO,
  COMPOSITION_RULES.SEQUENCE_NO,
  COMPOSITION_RULES.PROMPT_NO,
  COMPOSITION_RULES.COLUMN_NO,
  PROMPTS.FIELD_PROMPT
FROM
  STAFF_RETURN_ITEMS,
  COMPOSITION_RULES,
  PROMPTS
WHERE COMPOSITION_RULES.CAT_NO = STAFF_RETURN_ITEMS.CAT_NO
  AND COMPOSITION_RULES.SUB_CAT_NO = STAFF_RETURN_ITEMS.SUB_CAT_NO
  AND COMPOSITION_RULES.SUB_SUB_CAT_NO = STAFF_RETURN_ITEMS.SUB_SUB_CAT_NO
  AND PROMPTS.PROMPT_NO = COMPOSITION_RULES.PROMPT_NO
  AND STAFF_RETURN_ITEMS.CAT_NO = :P_CAT_NO
  AND STAFF_RETURN_ITEMS.SUB_CAT_NO = :P_SUB_CAT_NO
  AND STAFF_RETURN_ITEMS.SUB_SUB_CAT_NO = :P_SUB_SUB_CAT_NO
  AND STAFF_RETURN_ITEMS.DISPLAY_IN_REPORTS = 'T'
ORDER BY SEQUENCE_NO

Figure 44. SQL query used to define report structure

The query listed in figure 44 returns the structure of a value in the ‘Return Item’ table together with its category details, providing a level of indirection to the data that will appear in the report. The method of indirection is via a function that reads the structure according to the configuration rules (described in section 4.1.2.3) before resolving and returning the data pointed to by the rules. This function was named CF_DATA and, for simplicity, is presented as pseudo code in figure 45.
GET THE CURRENT COLUMN NUMBER
CASE COLUMN NUMBER OF:
  1 TO 6 : RETURN VARCHAR2
  7 TO 8 : RETURN NUMBER
  9    : RETURN LONG
  10 TO 11: RETURN DATE
END CASE

The SQL query and CF_DATA functions were then merged using the Oracle Report product’s graphical data model interface tools. The emergent model, illustrated in figure 46, separates the query into three groups as follows (relating to the tables shown in figure 17):

- **G_STAFF_NO**: Data related to the ‘Staff Return’ table.
- **G_CAT_NO**: Data related to the Category tables of ‘Category’ and ‘Sub Category’.
- **G_FIELD_PROMPT**: Data relating to the ‘Prompt’ and ‘Return Item’ tables.
Notably, the mechanism described in this section uses the flexible data model to provide reports governed by the same configuration rules used to configure dynamically the system’s user screens. To help demonstrate the flexible nature of the reports a selection of the sample reports has been included in appendix F. They were removed to an appendix to maintain brevity within the main document and, for the benefit of the reader.
4.3 Summary

This chapter has detailed the phases introduced in chapter three, namely those of analysis, design, and development of the sample application, and detailed and discussed those techniques and procedures that were used to implement them. Specifically detailed were the construction of the staff submission system in terms of flexible ‘front end’ and ‘back end’ development to satisfy the problem statement and associated requirements stated in chapter three.
Chapter 5: Findings

This chapter discusses the study’s findings, in relation to the research question stated in chapter one as: "How may the challenge of dynamic/flexible user requirements be met using data driven techniques in a 4GL-database environment?" Recalling, further, that the main research question consists of two components, both are now restated and each is addressed in turn.

5.1 Findings on Research Question, part (a).

"How may one model dynamic user requirements through an extension of current data modelling techniques?"

Part (a) of the research question was responded to by developing a sample application that investigated the viability of using an extension of existing data modelling techniques to capture and store a problem that is dynamic in nature. The author, in chapter two, has reviewed the exiguous literature occupied with the capture of dynamic requirements and, further, observed that few of the techniques described were practical enough for real application. An alternative approach of extending an existing data modelling technique was proffered as being superior to the creation of new modelling techniques as the tools and language facilities are already widely available.

To address part (a), the study extended standard modelling techniques, discussed in chapter two, defined in chapter three, and demonstrated in chapter four, for capture of the dynamic data requirements of a replacement Staff Submission System for ECU.
The enhanced E-R model reflects the requirement that a systems administrator may, post-implementation, whilst the system is live, wish to alter dynamically the category hierarchy and configuration rules of the system.

The resultant E-R model, discussed in chapter four, was extended to incorporate extra data thereby allowing the storage of dynamic mapping. This extension required neither new symbols nor relationships to be added to the currently accepted E-R modelling tool set. The extension’s success was validated by the ability of the Oracle CASE tool to convert the dynamic E-R model into database creation scripts, as the CASE tool strictly adheres to the standard E-R modelling precepts.

The author proposes that the successful extension of the E-R modelling technique yields two conclusions:

1. The capture of dynamic requirements using E-R modelling has been overlooked due to a lack of publications on the subject; and

2. Current, static E-R models may be extended through the study’s techniques to implement preventative maintenance and to provide extensibility.
5.2 Findings on Research Question, part (b).

“How may one implement user requirements of flexibility using data driven techniques in a 4GL environment?”

In response to research question, part (b), the study examined the feasibility of implementing those dynamic requirements, captured in response to research question part (a), in a 4GL environment. As stated in chapter three, the author chose the Oracle 4GL due to its ready availability and the use of the environment by previous studies into those parallel areas reviewed in chapter two.

The user requirements, as stated in chapter three, necessitated that the application be both flexible, to prove the point of the study, and functional, to demonstrate applicability of the study to satisfy real-world problems. Thus, the development of the application extended to demonstrate flexibility that mitigated costs of potential maintenance of the application’s data entry and reporting functions.

The study resulted in the creation of a Staff Submission System that allows an advanced user to alter the appearance and functionality of specific areas of the application. The flexibility was based on a database, generated from a dynamic E-R model. Further, a 4GL Oracle forms ‘front end’ was designed to ensure the application provided a pleasant and practical means to manage the flexible aspects of the system.
The completed application has undergone extensive acceptance testing by the author and the study’s clients, i.e. ECU staff, to verify system properties and, further, is undergoing commissioning and is expected to go “live” in July 2001.
Chapter 6: Conclusion

To introduce this final chapter, let us first examine the motivation of this study. The author, a programmer/analyst, is regularly contracted by organisations requiring changes to existing software systems. The author’s experiences and observations, plus those gathered from colleagues and from the literature, suggest that much remedial effort involved in system alterations during maintenance stems from a lack of foresight during initial analysis and design. In short, as implied in chapter one, this study was motivated by a desire to reduce that effort involved in perfective and adaptive maintenance, thereby enhancing the efficiency of programmers involved in maintenance activities.

In chapter two, literature, concerned with existing techniques for specifying and developing dynamic/flexible systems, was reviewed. The review concluded that while limited research pointed out the lack of suitable techniques, it failed to present published methods for practical solutions to the problem. Furthermore, published research that addressed ways to minimise maintenance effort through flexibility focussed on that of the ‘business rule’ or ‘front end’, and overlooked the fundamental importance of data flexibility.

In order to demonstrate a possible solution to the emergent problem of designing and developing a system with innate data flexibility, a ‘real life’ Staff Submission System, required by ECU, was selected. Accordingly, the Staff Submission System was
developed with a focus on the reduction of eventual maintenance that may be achieved through flexibility.

During the application’s development, flexibility was built-in into all possible aspects of the system. The resultant database incorporated dynamic mapping data that allowed runtime mapping from those database attributes, which required flexibility, to the user forms/reports where their requirements were not fully definable.

The successful creation and implementation in the study produces several implications for application designers and developers:

- A potential reduction in maintenance costs.
- The retention of use of established modelling techniques to accommodate dynamic requirements/abilities.
- The ability to develop application ‘front ends’ that, subsequently, may adapt to requirements changes with neither coding changes nor substantial recompilations and installations.
- An attendant increase in system life and flexibility.

Finally, the techniques established in this study are not limited to Oracle based applications and may be applied to database management systems in general. Through their use, future maintenance efforts might be mitigated to a point of major cost reductions in software maintenance, thereby releasing funds for the development of new or enhanced products.
Glossary

ECU: Edith Cowan University, 100 Joondalup Drive, Joondalup 6027, Western Australia.

Form: A form is a collection of objects with which a user may interact in order to view and modify database tables. Forms may consist of windows, canvases, text items, buttons and other windows dialog mechanisms. Typically a form will contain a number of different, but related, blocks.

LOV: A list of values (LOV) is a modal pick list and visual presentation of data contained in a record group. From such a list, users may select a single valid value, which is normally used to populate an item.

ODMG: “the Object Database Management Group undertakes continuing work on standards for object database management systems (ODBMSs)” (ODMG 2.0”, 1998).

Object Oriented (Approach): Comprises Object Oriented Analysis, Design and Programming, each of which, for clarity, is defined separately as follows, as taken from Booch (1994, p.38-39):

“Object-Oriented Analysis: a method of analysis that examines requirements from the perspective of the classes and objects found in the vocabulary of the problem domain.
Object-Oriented Design: a method of design encompassing the process of OO decomposition and a notation for depicting both logical and physical as well as static and dynamic models of the system under design.

Object-Oriented Programming: a method of implementation in which programs are organised as cooperative collections of objects, each of which represents an instance of some class, and whose classes are all members of a hierarchy of classes via inherited relationships.

PL/SQL: Procedural Language/Structured Query Language. PL/SQL is a procedural language developed by the Oracle Corporation for use in its products. It is functionally similar to many 3GLs and has a strong similarity to, and relationship with the language ADA. PL/SQL is used to provide a flexible means to enhance SQL code.

Record Groups: Structured sets of data used to facilitate interaction between the database and an application, most commonly using LOVs. Record groups are often perceived as virtual tables.

SQL: Structured Query Language is the standard language used in conjunction with relational database management systems. The American National Standards Institute (ANSI) and the International Standards Organisation (ISO) approved the standard jointly in 1992.
**Triggers:** A trigger is a section of code that is used to extend the functionality of an application. Each trigger contains one or more PL/SQL statements. A trigger may be associated with an event, such as when a button is selected, whereupon the trigger executes.

**UML:** “The Unified Modelling Language (UML) is a language for specifying, visualizing, constructing, and documenting the artefacts of software systems, as well as for business modelling and other non-software systems. The UML represents a collection of best engineering practices that have proven successful in the modelling of large and complex systems. The UML is the successor to the modelling languages found in the Booch, OOSE/Jacobson, OMT and other methods. Many companies are incorporating the UML as a standard into their development processes and products, which cover disciplines such as business modelling, requirements management, analysis & design, programming and testing.” (“UML”, 2001).

Submission System

DATA COLLECTION FOR THE MONTHS OF: ____________________________

ENTER INFORMATION RELATING TO COLLECTION PERIOD ONLY
PLEASE DO NOT USE ABBREVIATIONS

NAME: ________________________________________________________

TEACHING AND LEARNING

e.g. innovation and flexibility, internationalisation of curriculum, links with industry and professions, strategic partnerships and pathways, teaching grants and awards, achievement by undergraduate students.

RESEARCH GRANTS & ACTIVITIES

For research grants (please include amount granted, funding body, title of research project, co-researcher/s, collaborating organisations), research profile, research management, postgraduate research awards, achievements by postgraduate research students.

PUBLICATIONS

(Please give details of refereed publications in the data collection period)

Book: Authored - research:

Book Chapter (in A1 type Books):
Full written paper - refereed proceedings:

CONFERENCE PRESENTATIONS
Please give details of conferences attended, papers presented, significant role in the conference or organisation of the conference (please provide title of conference, paper presented, venue and dates).

AWARDS/RECOGNITION
Please give details of any significant staff achievements or awards (include title of award, awarding body and reason for award)

TV/RADIO/MEDIA PARTICIPATION
Please provide programme/article title, radio/TV station/newspaper, date, topic, reason for interview/article.

INTERNATIONALISATION OR INTERNATIONAL ACTIVITIES
e.g. strategic partnerships, international students, international visitors (please list name, duration and purpose of visit, activities undertaken, area of expertise, institution and country).

COMMERCIAL ACTIVITIES
Please give details of any commercial activities.
SERVICES AND SUPPORT

e.g. students (access, enrolments, support), equity and EEO, staffing (staff development, staff profile), IT, physical environment, safety.

MANAGEMENT

e.g. implementation of Strategic Plan, quality issues, general higher education issues.

STUDENT ACTIVITIES/ACHIEVEMENTS

(for inclusion in the Faculty Student Newsletter)

OTHER SIGNIFICANT ACTIVITIES (which are not covered by other categories)
Appendix B - Collection Category Setup

1. Teaching and Learning
   1.1 Teaching initiatives
      Name(s)
      School
      Description of initiative

   1.2 Teaching awards and grants
      Recipient(s)
      Awarding Body
      Title of award/grant
      Description
      Amount Granted

   1.3 Achievements by undergraduate students
      Name
      School
      Course
      Description
      Staff involved

2. Research and Creative Works
   2.1 Research Grants
      Recipient(s)
      Funding Body
      Title of research grant
      Amount granted
      Collaborating organisations

   2.2 Publications
      Book:
      Author
      Date
Creative works:
   Presenter
   Name of work
   Event
   Venue

2.3 Postgraduate student achievements
   Name of student
   School
   Description of achievement
   Staff involved

2.4 Research strategic alliances
   Institution/organisation
   Description of strategic alliance

2.5 Research Awards
   Recipient
   Awarding body
   Title of award
   Description of award

3. Community and professional service
   3.1 TV/radio/media participation
       Name
       Programme/article title
       Radio/TV station or publication
       Description
       Date

   3.2 Appointments to Boards or External Committees
       Position
       Name of Board or Committee
       Nominating group
       Date of tenure
3.3 Awards/recognition - significant achievements or awards

- Recipient
- Achievement/award
- Awarding body
- Reason for the award

3.4 Service/Initiatives

- Name
- School
- Description

3.5 Visitors

- Name
- Institution
- School/Centre
- Purpose
- Duration

4. International and Commercial activities

4.1 Strategic alliances/partnerships

- Name
- School
- Institution
- Description

4.2 International visitors

- Name
- Institution
- School
- Purpose of visit
- Duration

4.3 International students

- Name
- School
4.4 Commercial activities
   Name
   School
   Description

5. Other significant activities
   Name
   School
   Description
